A plane's engines are designed to move it forward at high speed. Photo: Newton's third law of motion explains how the engines and wings work together to make a plane move through the sky. The force of the hot exhaust gas shooting backward from the jet engine pushes the plane forward.

An air cycle machine (ACM) is the refrigeration unit of the environmental control system (ECS) used in pressurized gas turbine-powered aircraft. Normally an aircraft has two or three of these ACM. The work extracted by the expansion turbine is transmitted by a shaft to spin the pack's centrifugal compressor and an inlet fan.

An aircraft is a machine that is able to fly by gaining support from the air. It counters the force of gravity by using either static lift or by using the dynamic lift of an airfoil, or in a few cases the downward thrust from jet engines. Until that day, we have to content ourselves with last century's boring flying machines: planes and helicopters. To keep those aircraft working correctly, the world. Modified bleed air is introduced into the aircraft for pressurization, and in Machines (VCMs or Freon Units) are related in that each works on.
